Islet graft for treatment of type 1 diabetes mellitus

“Islet transplantation” is a treatment method for type 1 diabetes mellitus by transplanting insulin-producing pancreatic islets. To protect the transplanted cells from host immune reactions, methods for the encapsulation of islets have been pursued worldwide. Our research group developed the implantation grafts that encapsulate islets in the fiber-shaped hydrogel and succeeded in the control of the blood glucose concentration of diabetic mice and the subsequent retrieval of the implanted grafts. Currently, we focus on the fiber-shaped encapsulation of human iPS cell-derived islets, which can be a transformative donor-independent transplantation therapy.

Transplantation of the fiber encapsulating islet cells into kidney capsule.
