Local Energy Chemical Engineering

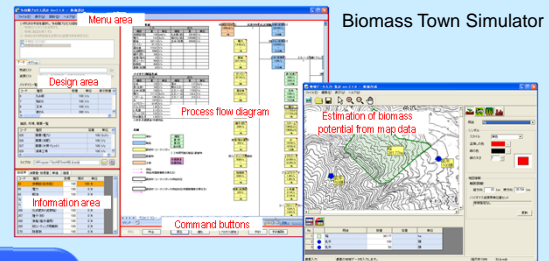

We are conducting researches on the development of key technologies and their fundamentals, based on chemical engineering, as follows.

- Combination of saccharification, fermentation and separation for bioethanol production
- Behavior of nitrogen and phosphorus in carbonization process
- Electrochemical oxidation of charcoals
- Biomass storage and its effects on the saccharification/fermentation

Fundamentals of bioethanol technologies

The final goal of this project is to promote the biomass-orientated regional material and energy circulations, to nurture the growth of the sustainable society. In order to create reasonable scenarios for the regional biomass utilization system, we have drawn up a plan of "Biomass Town" to meet the actual situation of local communities. We have examined methods to design and analysis of the biomass utilization systems based on the concept of Biomass Town. The methods involved analyses algorithms to deal with the following units: i.e., biomass availability, biomass collection/transportation, biomass utilization process design and environmental impact. Integrating the algorithms, we developed a Biomass Town Simulator.

Biomass Town Simulator

Electrochemical oxidation of charcoal (Direct carbon fuel cell)

Laboratory works
➤ Technological developments

Computer works

➤ Establishment of reasonable biomass utilization systems

Key Technologies

Design and evaluation

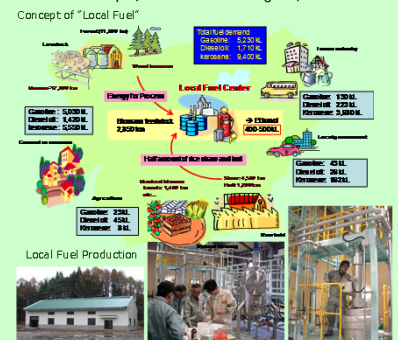

Process engineering

Demonstrations

Pilot plant works

➤ Towards practical productions

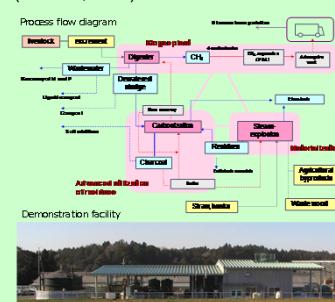

Development of Small-scale Bioethanol System Based on "Local Fuel" Concept (Shinano-mach, Nagano)

Field works

➤ Comprehensive evaluations

Demonstration of Local Biogas Utilization (Katori-shi, Chiba)

Demonstration of Biomass Town System in South-east Asia (Thai My Village, Vietnam)

Small-scale bioethanol system for biomass town
