[Demand Side Electric Power System Utilizing IoT]

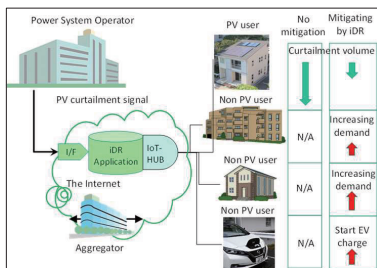

Department of Human and Social Systems

Engineering of Distributed Energy Resources Utilizing

Currently, avoiding global warming has become a big issue globally, and the concrete plan of building a so-called decarbonized society is gathering interest. Of course, solar power and wind power will play an important role of it. There are various types of renewable energies, however, especially, solar and wind power generation does not obey human order as it is called "Variable Renewable Energy (VRE)". It is just up to the weather or wind and fundamentally different power source from the conventional thermal power generation.

At present, VRE output fluctuations are absorbed mainly by changing the output of thermal power generation in the reverse pattern and the frequency are maintained. But it is approaching the limit. In fact, in the Kyushu area, the situation which we have to curb the output of the solar power has happened so often, since the number of solar power generation facilities has increased too much. In the future, in order to increase VRE more, it will be necessary not only to increase these facilities, but also to change the structure of the demand side, i.e., user of electricity. Socio-economic are not acted for the convenience of energy, but it seems that we need to change mind now and act for the convenience of energy. Of course, it is also necessary to introduce a low-cost system so that socio-economic activities are not affected. A paradigm shift is required for us right now.

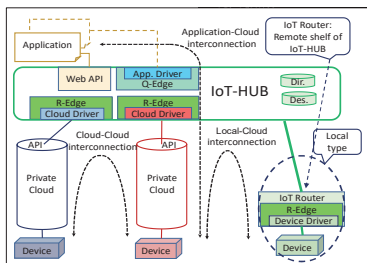

For example, we will need a new mechanism such as charging an electric vehicle (EV) according to the VRE status, even when we are away from home. Since it is possible that the places where a lot of VRE power is generated is not require additional power, these balancing mechanism should work in wide area like entire Kanto area. Fortunately, a technology called IoT (Internet of Things) has been developed, and it seems that we can create a power system that can introduce more VRE using IoT. My laboratory will proceed with research and development of elemental technologies and social implementation method while assuming such a mechanism.

Increase and Decrease of the Demand by Aggregator according to the Output status of Variable Renewable Energy Resources

Design of a Protocol-free Mechanism for Interconnecting and Controlling all Demand Equipment

Prototype Development of Cloud-Cloud Interconnection Infrastructure for IoT

Social Implementation of Cloud-Cloud Interconnection Infrastructure for IoT (Press Conference in May 29, 2019)
